## Chem 633: Advanced Organic Chemistry Midterm 2

Please answer the following questions *clearly and concisely*.

Write your answers in the space provided.

Write your initials on each page you want graded.

There are 15 total pages to this exam. Please be sure your copy has 15 pages before you begin.

Molecular models are allowed.

Calculators are unnecessary and prohibited.

Problem	Points
1	/10
2	/10
3	/10
4	/20
5	/22
6	/28
TOTAL	/100

1. (10 points) Please state whether the following groups are homotopic, enantiotopic or diastereotopic. (No explanation necessary)

2. (10 points) Please draw a reasonable arrow-pushing mechanism for the following transformation (Grossman, p. 329).

3. (10 points) Please draw a reasonable arrow-pushing mechanism for the following transformation (Rawal, V. H.; Newton, R. C.; Krishnamurthy, V. *J. Org. Chem.* **1990**, *55*, 5181).

4. (20 points) Please consider the rearrangement of (–)-chlorismate to prephanate in answering the following questions (Andrews, P. R.; Smith, G. D.; Young, I. G. *Biochemistry* **1973**, *12*, 3492).

(a) Is this reaction endothermic or exothermic? (No explanation necessary)

(b) Do you expect the transition state of this reaction to be early or late? (No explanation necessary)

(c) Explain how one can experimentally determine  $\Delta H^{\ddagger}$  and  $\Delta S^{\ddagger}$  of this process. Include all equations and graphs that are necessary for analyzing the data.

(d) The experimentally determined entropy of this rearrangement is given below. Provide an explanation of the magnitude and sign of entropy.

$$\Delta S^{\mp} = -12.9 \pm 0.4 \text{ e.u.}$$

Initials:

5. (22 points) As a model for highly regioselective epoxide-opening cascades that form ladder polyethers, Byers and Jamison examined the cyclization of epoxide **1** (Byers, J. A.; Jamison, T. F. *J. Am. Chem. Soc.* **2009**, *131*, 6383).

(a) Please draw clear 3-dimensional representations of the lowest energy conformations of **2** and **3**.

(b) The researchers compared the rates of this reaction in H<sub>2</sub>O vs. D<sub>2</sub>O and found that  $k_{H2O}/k_{D2O} = 1.33$ . What does this suggest about the mechanism of this reaction? (Answer in less than 20 words.)

(c) Jamison proposes that two pathways lead to products **2** and **3**, of which the pathway via intermediate **A** is unselective and the pathway via intermediate **B** is highly selective.

Derive rate laws for the formation of **2** and **3**. You may assume that the equilibrium between **1**, **A** and **B** is fast. Use the constants depicted in the scheme above. Express your rate laws in terms of [**1**] and  $[H_2O]$ .

- (5 continued)
- (d) This reaction could also be performed in DMSO with a large excess of  $D_2O$  relative to epoxide **1**. Under these conditions, the following data was collected. In these graphs,  $k_2$  is the overall observed rate constant for the formation of **2**, and  $k_3$  is the overall observed rate constant for the formation of **3**.

In the formation of  $\mathbf{2}$ , what is the kinetic order in [D<sub>2</sub>O]?

In the formation of 3, what is the kinetic order in [D<sub>2</sub>O]?

(5 - continued)

\_\_\_\_

(e) Please show that the linear behavior in the following graph is consistent with the rate laws you derived for Jamison's proposed mechanism.

Initials:

6. (28 points) Deprez and Sanford have recently reported the careful mechanistic study of the palladium-catalyzed C–H arylation reaction (Deprez, N. R.; Sanford, M. S. *J. Am. Chem. Soc.* **2009**, *131*, 11234).

(a) The originally proposed mechanism for this reaction is shown below.

Please write a "one plus" catalytic rate expression for this catalytic cycle. You may use generic observable constants for each of the terms in the rate law ( $C_1$ ,  $C_2$ , etc.).

(b) Assuming that the second step  $(\mathbf{A} \rightarrow \mathbf{B})$  is rate-limiting and all subsequent steps to regenerate  $\mathbf{Pd}$  are rapid and irreversible, write a simplified "one plus" catalytic rate expression. Use the rate constants depicted in the catalytic cycle above, and assume that any steps prior to the rate-limiting step are rapid and reversible compared with the rate-limiting step. Express your rate law in terms of [1], [I<sup>III</sup>], and [Pd]<sub>total</sub>.

(c) The authors wondered if this reaction proceeds via a radical intermediate. Please propose **2** experiments to test for the existence of such an intermediate.

(d) Using initial rate experiments, the following correlations between rate and the concentrations of  $I^{III}$ , Pd, and 1 have been determined. Please state the rate dependence (first order, second order, etc.) on each of these species.

(6d - continued)

## (6 - continued)

(e) Based on these results and the observation that **7** was the catalyst resting state and **8** was the iodine resting state, Sanford proposed a new mechanism for this reaction (shown below). *Write a rate law for this transformation.* You may assume any steps prior to the rate-limiting (or turnover limiting) step are rapid and reversible compared with the rate-limiting step and that subsequent steps to regenerate **3** are rapid and irreversible. Express your rate law in terms of **7**, **8**, and **1** (the observable species).

## (6 - continued)

(f) The authors also performed a Hammett study with substituted iodonium reagents in place of **I**<sup>III</sup>. What does the following data tell you?

## (6 - continued)

(g) In a final set of experiments, the authors performed isotope effect experiments. Why are the isotope effects different in these two experiments? (Answer in less than 20 words.)

Experiment 1

Experiment 2
